DATA ANALYST TAKE-HOME · 09/10/2026

What predicts a customer paying their first monthly fee?

First-30-day behaviour of 5,000 customers who signed up in 2024

Damian Adamski · For the Head of Product and the Head of Data

THE ANSWER UP FRONT

Activation, allowance and family login drive first-fee collection

Q1 · BEHAVIOURS

Allowance and family login

Setting up an allowance (+25pp) and parent and child logging in together (+20pp) are the strongest signals. A declined card payment is the main warning sign (−12pp).

Q2 · SEGMENTS

Channel and platform, not plan tier

Referral customers pay most (77%), TikTok least (54%), and Web trails iOS by 8pp. The gaps hold after accounting for behaviour. Plan tier makes no difference.

Q3 · RECOMMENDATIONS

Three changes to test

Activation nudges, allowance and family login built into onboarding, and a top-up prompt after a declined payment, each run as an A/B test.

pp = percentage points. Behaviour figures use activated customers (n = 4,236), holding other factors equal.

THE FUNNEL

15% never activate their card, and none of them pay

34%

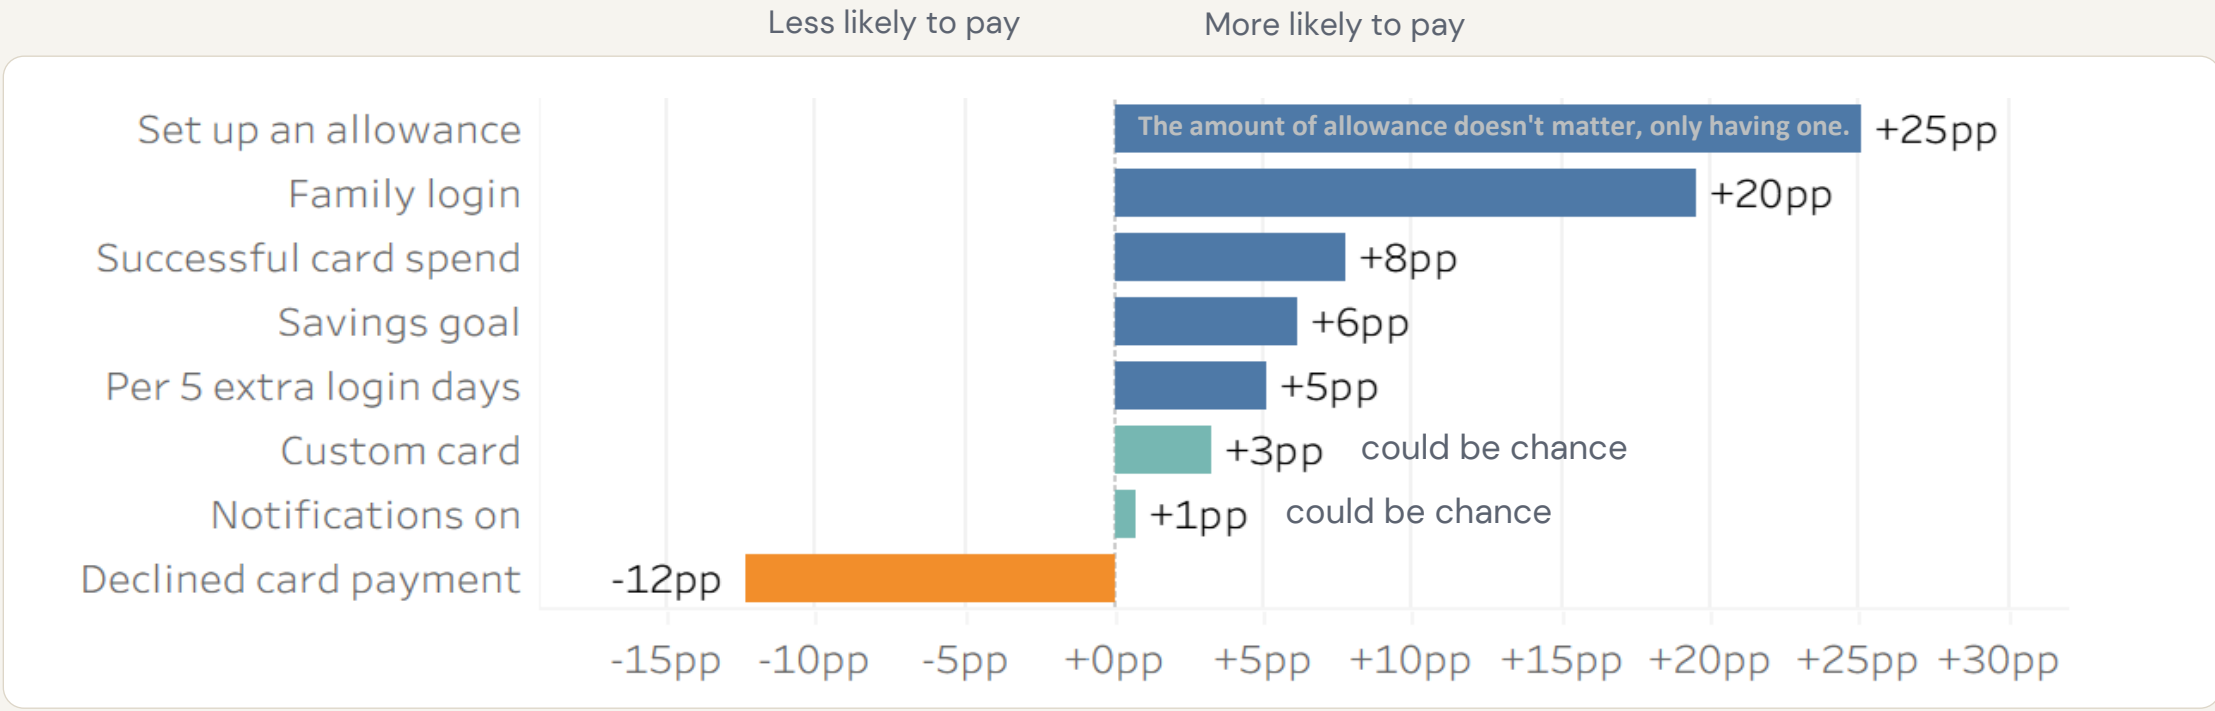

of customers who didn't pay never activated their card (764 of 2,243).

Activation is its own lever. The behaviour analysis that follows uses the 4,236 activated customers.

Data checked with 22 quality rules: clean apart from 4 inconsistent rows, kept and flagged (no effect on results).

BEHAVIOURS

Allowance and family login matter most; declined payments hurt

Change in the chance of paying the first fee, holding the other behaviours, platform, tier and channel equal (logistic regression, activated customers, n = 4,236). Family login = parent and child both log in. Teal = not statistically significant.

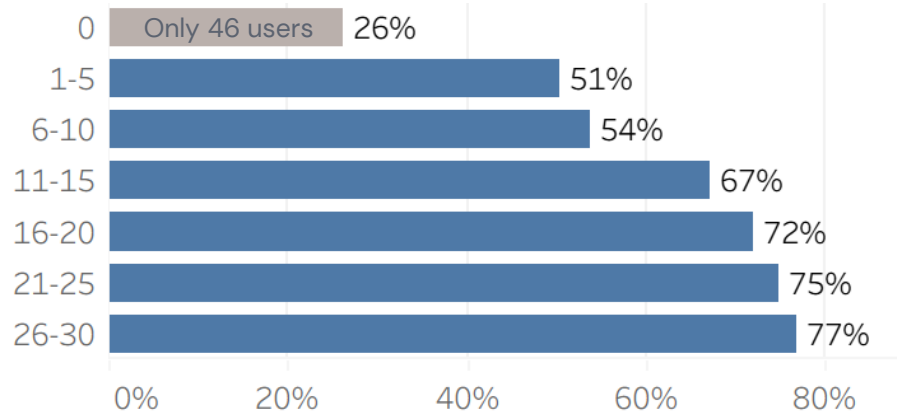

HABITS

Families with both habits almost always pay

Fee rate by allowance and family login

	Family login	No family login
Allowance	94% n = 419	77% n = 1,227
No allowance	73% n = 612	49% n = 1,978

Fee rate by login days (first 30 days)

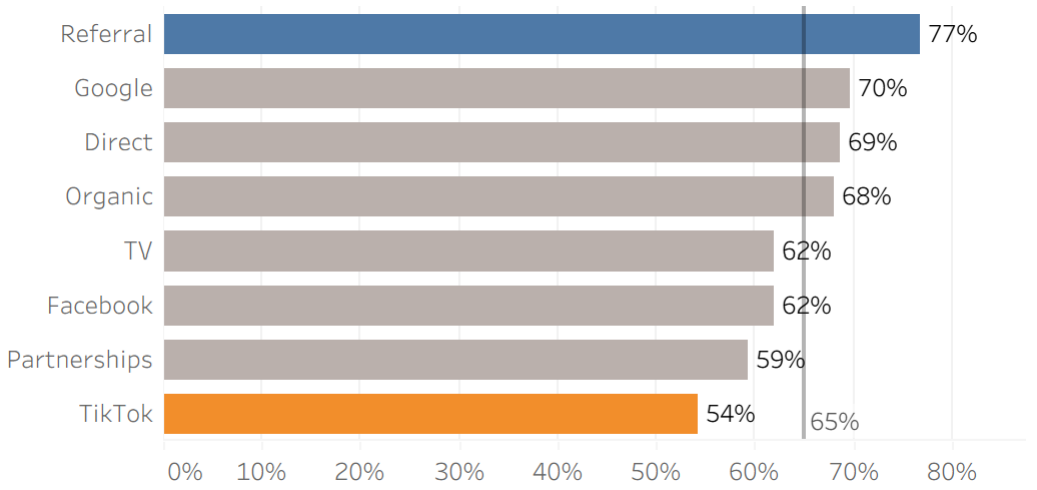

Activated customers, n = 4,236. The two habits mostly add up rather than multiply.
Login days = the number of different days the parent logged into the app during their first 30 days.

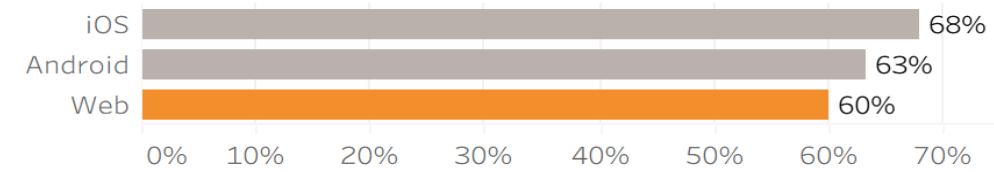

SEGMENTS

Channel and platform matter; plan tier does not

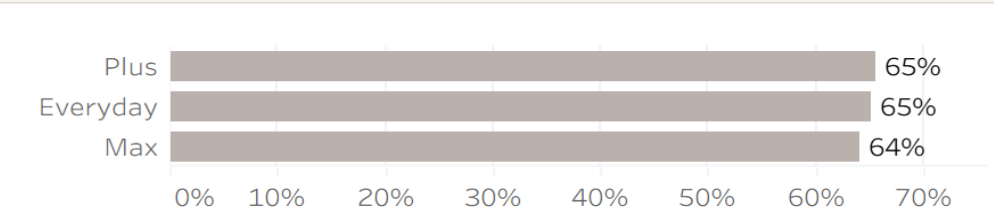

Fee rate by acquisition channel

Fee rate by platform

Fee rate by plan tier

no real difference

Activated customers; average 65%. Channel and platform gaps remain after accounting for behaviour (TikTok -14pp and Referral +8pp vs Organic; Web -8pp vs iOS).

RECOMMENDATIONS

Three changes to test

1 · ACTIVATION

Nudge customers to activate their card

Why: 34% of non-payers never activated, and nobody pays without activating.

Test: card-arrived reminders and step-by-step activation help in the app.

+1.8pp

of all signups paying (range +1.0 to +3.3pp)

2 · ONBOARDING

Build allowance and family login into onboarding

Why: the two strongest habits (+25pp, +20pp); 94% pay with both.

Test: a pre-filled weekly allowance step and a prompt for the child's first login.

+1.1pp

of all signups paying (range +0.3 to +2.4pp)

3 · DECLINED PAYMENTS

Prompt a top-up after a declined payment

Why: the main warning sign (-12pp); 1 in 5 activated customers has a decline.

Test: a real-time alert to the parent with the reason and a one-tap top-up.

+0.4pp

of all signups paying (range +0.1 to +0.8pp)

Impact = extra first-fee payers as a share of all signups, central scenario. Assumes only part of each link is causal.

MEASURING SUCCESS

Each change runs as an A/B test on first-fee collection

Element	What we measure
Primary metric	Share of all signups who pay their first fee (55% today)
Leading signals	Activation within 14 days · allowance set up within 7 days · top-up within 24h of a decline
Guardrails	Time to activate · support contacts · cancellations · second-month fee
Design	New signups split 50/50 at random; success rule agreed before launch

Customers needed per group

To detect +2pp	**9,700**
To detect +3pp	**4,300**
To detect +5pp	**1,500**

Baseline 55%, 95% confidence, 80% power.

Caveats: associations, not proven causes · fee timing and reasons for failed fees to confirm · dummy data. **Next:** an early-warning score at day 7 to target these interventions.
